Practical -1

Aim: Understanding the Sensor Node Hardware. (For Eg. Sensors, Nodes (Sensor mote), Base Station, Graphical User Interface.)

i. Components

A wireless sensor network (WSN) is a hardware and software package that typically consists of four parts (see Figure 1):

a) 'Sensors' connected to each node by a wired connection. In our case, we use sensors that can measure soil moisture, electrical conductivity, soil temperature, water pressure, flow rate, or a range of weather variables (light, air temperature, wind, humidity, etc.).

b) 'Nodes' collect the data from sensors and transmit that to a 'base station' computer using a one way (in the case of monitoring) or two---way (in the case of monitoring and control) radio. Nodes can simply monitor environmental and soil conditions or can be used to make control decisions.

This nR5 (Decagon Devices, Inc. Pullman, WA) node is powered off of 5—AA batteries and is connected to 5 soil moisture sensors via stereo ports. The nR5 node is also capable of controlling irrigation valve(s), based on user—defined settings.

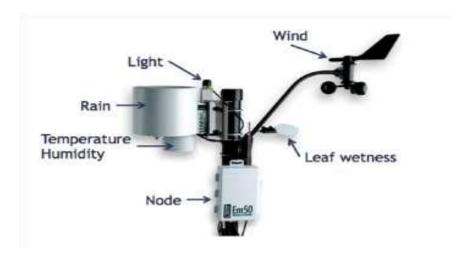

- c) 'Base Station' computer connects the system to the internet, so that data collected by the nodes, then transmitted to the base station computer, can be viewed anywhere an internet connection is available.
- d) 'Graphical User Interface' is the web---based software package, that allows the data collected by sensors to be viewed. The software is also used to set irrigation parameters.

The graphical user interface above depicts the volumetric water content (soil moisture) as horizontal lines and irrigation events and amounts as bars. Notice the increase in soil moisture after each irrigation event.

Not every WSN will have all four components, but to get optimal functionality the systems developed as part of this project do.

A very simple WSN example that many can relate to is that of the wireless environmental monitoring system used by the National Weather service (NWS). You have probably seen these at a local airport or school. In this case, sensors measure environmental conditions and send this data to a node that wirelessly transmits the data using a cell signal or wireless signal to a base-station computer where NWS employees (and you) can view the current temperature (or rainfall/dew point, wind, etc.) via a website or application('app').

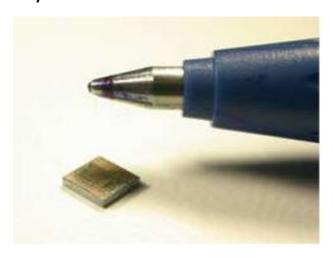

Typical environment monitoring sensors that you would see at a national weather service(NWS) monitoring station. These same components can be used in a wireless sensor by a specialty crop producer.

Practical -2

Aim: Exploring and understanding TinyOS computational concepts:- Events, Commands and Task.

- -nesC model
- -nesC Components

TinyOS and nesC

Outline

- Wireless sensor networks and TinyOS
- Networked embedded system C (nesC)
 - -Components
 - -Interfaces
 - -Concurrency model
 - -Tool chain
- Issues / conclusion

Wireless Sensor Networks

- Vision: ubiquitous computing
- Extreme dynamics
- Interact with environment using sensors and radio
- Immense scale
- Limited access
- Small, cheap, low-power systems

Concepts in Sensor Networks

- In-network processing and data aggregation
 - Radio activity 1000 times as expensive as processing
- Duty-cycling: different modes of operation
 - Power down unused hardware
- Systems run a single application
- Applications are deeply tied to hardware

-Require customized and optimized OS

Challenges

- Limited resources: energy consumption dominates
- Concurrency: driven by interaction with environment
- Soft real-time requirements
- Reliability: reduce run-time errors, e.g. races
- High diversity of platforms
- No well-defined software/hardware boundary

TinyOS

- Component-based architecture
 - Reusable system components: ADC, Timer, Radio
- Tasks and event-based concurrency
 - No user-space or context switching supported by hardware
 - Tasks run to completion only preempted by interrupts
- All long-latency operations are split-phase
 - Operation request and completion are separate functions

Introducing nesC

- A "holistic" approach to networked embedded systems
- Supports and reflects TinyOS's design
- Extends a subset of C
- A static language
 - -All resources known at compile-time
 - -Call-graph fully known at compile-time

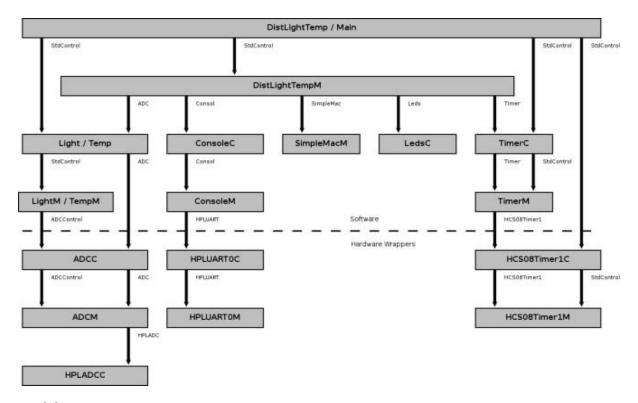

Design Decisions for nesC

- Components
- Bidirectional interfaces
- Simple expressive concurrency model
- Whole-program analysis

Components

- Challenge: platform diversity, flexible SW/HW boundary, applications deeply tied to hardware
- Encourages modular design
- Restrict access to private data
- Allow underlying implementations to be replaced easily
- Can abstract HW using thin wrappers
- Allow specialization of applications to hardware

Example Component Graph

Module Components

- Modules implement application code
- Modules have private state
 - -Sharing of data among components is discouraged
- Convention:
 - -Module names end with 'M', e.g. BlinkM
 - -Module variables start with 'm_', e.g. m_timers

Configuration Components

- Configurations wire other components together
- All applications have a top-level configuration
- A component interface may be wired zero or more times
 - -Used for StdControl to implement power management
- Convention:
 - -Configuration names end with 'C', e.g. TimerC (unless it is the top-level configuration ;-)

Bidirectional Interfaces

- Challenge: flexible SW/HW boundary and concurrency
- Support split-phase operations
- Commands: call down the component graph
 - -Implemented by provider
- Events: call up the component graph
 - -Implemented by user

Concurrency Model

- Challenge: extreme dynamics and soft real-time requirements
- Cooperative scheduling
- Light-weight tasks
- Split-phase operations: non-blocking requests
- Built-in atomic sections
 - Limited crossing of module boundaries

Sources of Concurrency

- Tasks
 - Deferred computation
 - Run sequential and to completion
 - Do not preempt
- Events
 - Run to completion, and may preempt tasks and events
 - Origin: hardware interrupts or split-phase completion

Whole-Program Analysis

- Compilation can examine complete call-graph
 - Remove dead-code
 - Eliminate costly module boundary crossings
 - Inline small functions
- Back-end C compiler can optimize whole program
 - Perform cross component optimizations
 - Constant propagation, common sub-expression elimination
- Allows detection of race conditions

Synchronous and Asynchronous

- Asynchronous code (AC):
 - Code reachable from at least one interrupt handler
 - Events signaled directly or indirectly by hardware interrupts Synchronous code
 (SC): "Everything else ..."
 - Primarily tasks

Detecting Race Conditions

- Invariant: *SC is atomic with respect to other SC* Two claims about updates for AC/AC and SC/AC:
 - Any update to shared state from AC is a potential race condition
 - Any update to shared state from SC that is also updated from AC is a potential race
 - condition Race-free invariant enforced at compile time:
 - Updates to shared state is either SC only or in atomic section

Dealing with Race Conditions

- Use atomic sections to update shared state
 - atomic { shared_var = 1; }
- Convert code with updates to shared state to tasks
- Mark false positive with norace qualifier
 - norace uint8_t variable;

The nesC Toolchain: nesdoc

- Generate code documentation using simple tags
- Same concept as javadoc
- Can generate a component graph using dot

The nesC Toolchain: nescc

- The nesC compiler for TinyOS
- Implemented as an extension to GCC
- Called via TinyOS wrapper ncc
- Input: path to TinyOS code + nesC files
 - Platform code implements API of macros and functions in C
- Output: C code or object code (if supported by GCC)

The nesC Toolchain: ncg and mig

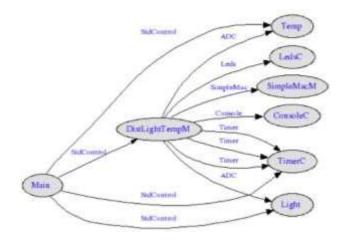

- Allows integration with Java code
- Typical use: interact with network through base station
- ncg extract constants from nesC files
 - Generates class that contains constants
- mig message interface generator for nesC
 - Generates class that encodes and decodes messages

Issues for nesC

- Problem for data shared across components
 - False positives for buffer swapping
- Problem for data shared between split-phase operations
 - Event can potentially fire if other components access HW
- Some TinyOS idioms are not well expressed
 - Parameterized interfaces each with private state

Issues for Applications

- Focus early on modeling it as a state-machine
- Design duty-cycling from the start
 - Affect the state-machine so hard to add later
- Abstracting functionality into components
 - Makes it harder to access shared state:
 encapsulate shared state in a separate module
- Configuring TinyOS for the application needs

By default there can only be 8 posted tasks

Conclusions for nesC

- Bidirectional interfaces fit the TinyOS model
- Components are a good abstraction
- Concurrency model meets requirements in applications
- The restrictions in nesC introduce practical problems
- Not limited to the domain of embedded systems

Practical -3

Aim: Understanding TOSSIM for

- Mote-mote radio communication
- Mote-PC serial communication

Steps:

a) TOSSIM for Mote-mote radio communication

Introduction:

TOSSIM is a discrete event simulator for TinyOS sensor networks. Instead of compiling a TinyOS application for a mote, users can compile it into the TOSSIM framework, which runs on a PC. This allows users to debug, test, and analyze algorithms in a controlled and repeatable environment. As TOSSIM runs on a PC, users can examine their TinyOS code using debuggers and other development tools. This document briefly describes the design philosophy of TOSSIM, its capabilities, its structure. It also provides a brief tutorial on how to use TOSSIM for testing or analysis.

TinyOS provides a number of *interfaces* to abstract the underlying communications services and a number of *components*that *provide* (implement) these interfaces. All of these interfaces and components use a common message buffer abstraction, called message_t, which is implemented as a nesC struct (similar to a C struct). The message_t abstraction replaces the TinyOS 1.x TOS_Msg abstraction. Unlike TinyOS 1.x, the members of message_t are opaque, and therefore not accessed directly.

Basic Communications Interfaces

There are a number of interfaces and components that use message_t as the underlying data structure.

Let's take a look at some of the interfaces that are in ourselves with the general functionality of the communications system:

- Packet Provides the basic accessors for the message_t abstract data type. This interface
 provides commands for clearing a message's contents, getting its payload length, and getting a
 pointer to its payload area.
- Send Provides the basic *address-free* message sending interface. This interface provides commands for sending a message and canceling a pending message send. The interface provides an event to indicate whether a message was sent successfully or not. It also provides convenience functions for getting the message's maximum payload as well as a pointer to a message's payload area.
- Receive Provides the basic message reception interface. This interface provides an event for receiving messages. It also provides, for convenience, commands for getting a message's payload length and getting a pointer to a message's payload area.
- PacketAcknowledgements Provides a mechanism for requesting acknowledgements on a perpacket basis.
- RadioTimeStamping Provides time stamping information for radio transmission and reception.

Components

A number of components implement the basic communications and active message interfaces. Let's

take a look at some of the components in /tos/system directory. You should be familiar with these the

components because your code needs to specify both the *interfaces* your application *uses* as well as the *components* which *provide* (implement) those interfaces:

- AMReceiverC Provides the following interfaces: Receive, Packet, and AMPacket.
- AMSenderC Provides AMSend, Packet, AMPacket, and PacketAcknowledgements as Acks.
- AMSnooperC Provides Receive, Packet, and AMPacket.
- AMSnoopingReceiverC Provides Receive, Packet, and AMPacket.
- ActiveMessageAddressC Provides commands to get and set the node's active message address.
 This interface is not for general use and changing a node's active message address can break the network stack, so avoid using it unless you know what you are doing.

Compiling TOSSIM

TOSSIM is a TinyOS library. Its core code lives in tos/lib/tossim. Every TinyOS source directory has an optionalsim subdirectory, which may contain simulation implementations of that package. For example, tos/chips/atm128/timer/sim contains TOSSIM implementations of some of the Atmega128 timer abstractions.

To compile TOSSIM, you pass the sim option to make:

\$ cd apps/Blink

\$ make micaz sim

Running TOSSIM with Python

Go into the RadioCountToLeds application and build TOSSIM:

\$ cd tinyos-2.x/apps/RadioCountToLeds

\$ make micaz sim

We'll start with Python in interactive mode. To start the Python interpreter, type:

\$ python

b) TOSSIM for Mote-PC radio communication

Packet sources and TestSerial

The first step is to check that you are able to get your PC to communicate with a mote. Most motes have a serial port or similar interface. For example, the mica family can directly control a serial port: programming boards basically connect the mote's serial port pins to the actual serial port on the board. Telos motes also have a serial interface, but it talks to their USB hardware, which is similar in functionality but very different in terms of cables and connectors.

The basic abstraction for mote-PC communication is a **packet source**. A packet source is exactly that: a communication medium over which an application can receive packets from and send packets to a mote. Examples of packet sources include serial ports, TCP sockets, and the SerialForwarder tool.

Most TinyOS communication tools take an optional parameter, which allows you to specify the packet source as a string. For example:

\$ java net.tinyos.tools.Listen -comm serial@COM1:telos

tells the Listen tool to use the COM1 serial port (on a Windows machine) at the correct speed for a telos mote, while

\$ java net.tinyos.tools.Listen -comm serial@/dev/ttyS0:micaz

tells Listen to use the serial port /dev/ttys0 (on a UNIX machine) at the correct speed for a micaz mote.

The first step to testing your serial port is to install the apps/tests/TestSerial application on a mote. This application sends a packet to the serial port every second, and when it receives a packet over the serial port it displays the packet's sequence number on the LEDs.

Once you have installed <code>TestSerial</code>, you need to run the corresponding Java application that communicates with it over the serial port. This is built when you build the TinyOS application. From in the application directory, type:

\$ java TestSerial

If you get a message like

The java class is not found: TestSerial

it means that you either haven't compiled the Java code (try running make platform again) or you don't have . (the current directory) in your Java CLASSPATH.

Because you haven't specified a packet source, TestSerial will fall back to a default, which is a SerialForwarder. Since you don't have a SerialForwarder running, TestSerial will exit, complaining

that it can't connect to one. So let's specify the serial port as the source, using _ parameter as the

described above. The syntax for a serial port source is as follows:

```
serial@<PORT>:<SPEED>
```

PORT depends on your platform and where you have plugged the mote in. For Windows/Cygwin platforms, it is COMN, where N is the port number. For Linux/UNIX machines, it is $footnote{Idev/ttys}N$ for a built-in serial port, or one of $footnote{Idev/ttyusb}N$ or $footnote{Idev/ttyusb}N$ for a serial-over-USB port. Additionally as we saw in $footnote{Idesv}N$ for a serial-over-USB port world writeable. As superuser, execute the following command:

chmod 666 serialport

The SPEED can either be a numeric value, or the name of a platform. Specifying a platform name tells the serial packet source to use the default speed for the platform. Valid platforms are:

The Java file support/sdk/java/net/tinyos/packet/BaudRate.java determines these mappings. Unlike in TinyOS 1.x, all platforms have a common serial packet format. Following the table, these two serial specifications are identical:

serial@COM1:micaz serial@COM1:57600

If you run TestSerial with the proper PORT and SPEED settings, you should see output like this:

Sending packet 1

Received packet sequence number 4

Sending packet 2

Received packet sequence number 5

Sending packet 3

Received packet sequence number 6

Sending packet 4

Received packet sequence number 7

Received packet sequence number 8

Sending packet 5

Received packet sequence number 9 Sending packet 6

and the mote LEDs will blink.

MOTECOM

If you do not pass a -comm parameter, then tools will check the MOTECOM environment variable for a packet source, and if there is no MOTECOM, they default to a SerialForwarder. This means that if you're

always communicating with a mote over your serial port, you can just and no longer set

to specify the -comm parameter. For example:

export MOTECOM=serial@COM1:19200 # mica baud rate
export MOTECOM=serial@COM1:mica # mica baud rate,
again
export MOTECOM=serial@COM2:mica2 # the mica2 baud rate, on a different serial port
export MOTECOM=serial@COM3:57600 # explicit mica2 baud rate

Try setting your MOTECOM variable and running TestSerial without a -comm parameter.

BaseStation and net.tinyos.tools.Listen

BaseStation is a basic TinyOS utility application. It acts as a bridge between the serial port and radio network. When it receives a packet from the serial port, it transmits it on the radio; when it receives a packets over the radio, it transmits it to the serial port. Because TinyOS has a toolchain for generating and sending packets to a mote over a serial port, using a BaseStation allows PC tools to communicate directly with mote networks.

Take one of the two nodes that had BlinkToRadio (from lesson 3) installed and install BaseStation on it. If you turn on the node that still has BlinkToRadio installed, you should see LED 1 on the BaseStation blinking. BaseStation toggles LED 0 whenever it sends a packet to the radio and LED 1 whenever it sends a packet to the serial port. It toggles LED 2 whenever it has to drop a packet: this can happen when one of the two receives packets faster than the other can send them (e.g., receiving micaZ radio packets at 256kbps but sending serial packets at 57.6kbps).

BaseStation is receiving your BlinkToRadio packets and sending them to the serial port, so if it is plugged into a PC we can view these packets. The Java tool Listen is a basic packet sniffer: it prints out the binary contents of any packet it hears. Run Listen, using either MOTECOM or a -comm parameter:

\$ java net.tinyos.tools.Listen

Listen creates a packet source and just prints out every packet it sees. Your output should look something like this:

```
00 FF FF 00 00 04 22 06 00 02 00 01
00 FF FF 00 00 04 22 06 00 02 00 02
00 FF FF 00 00 04 22 06 00 02 00 03
00 FF FF 00 00 04 22 06 00 02 00 04
00 FF FF 00 00 04 22 06 00 02 00 05
00 FF FF 00 00 04 22 06 00 02 00 06
00 FF FF 00 00 04 22 06 00 02 00 07
00 FF FF 00 00 04 22 06 00 02 00 08
00 FF FF 00 00 04 22 06 00 02 00 09
00 FF FF 00 00 04 22 06 00 02 00 0A
00 FF FF 00 00 04 22 06 00 02 00 0B
```

Listen is simply printing out the packets that are coming from the mote. Each data packet that comes out of the mote contains several fields of data. The first byte (00) indicates that this is packet is an AM packet. The next fields are the generic Active Message fields, defined in tinyos-

2.x/tos/lib/serial/Serial.h. Finally, the remaining fields are the data payload of the message, which was defined in BlinkToRadio.h as:

```
typedef nx_struct BlinkToRadioMsg {
    nx_uint16_t nodeid;
    nx_uint16_t counter;
} BlinkToRadioMsg;
```

The overall message format for the BlinkToRadioC application is therefore (ignoring the first 00 byte):

- **Destination address** (2 bytes)
- Link source address (2 bytes)
- Message length (1 byte)
- Group ID (1 byte)
- Active Message handler type (1 byte) ☐ Payload (up to 28 bytes):
- source mote ID (2 bytes)
- sample counter (2 bytes)

So we can interpret the data packet as follows:

dest addr link source addr msg len groupID handlerID source addr counter									
ff ff	00 00	04	22	06	00 02	00 OB			

The link source address and source address field differ in who sets them. The serial stack does not set the link source address; for Blink, it should always be $00\ 00$. Blink sets the source address to be the node's ID, which depends on what mote ID you installed your BlinkToRadio application with. The

default (if you do not specify and ID) is $00 \ 01$. Note that the data is sent by the mote in big-endian format; for example, $01 \ 02$ means 258 (256*1 + 2). This format is independent of the endianness of the processor, because the packet $\frac{nx_struct}{nx_struct}$ format is an , which is a network format, that is,

big-endian and byte-aligned. Using nx_struct (rather than a standard C_struct) for a message payload ensures that it will work across platforms.

As you watch the packets scroll by, you should see the counter field increase as the BlinkToRadio app increments its counter.

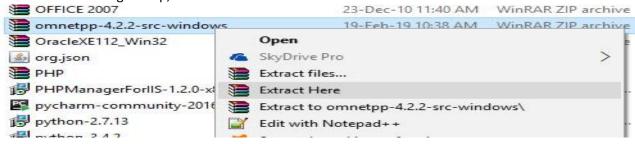

Practical-4

Aim: Create and simulate a simple adhoc network Steps:

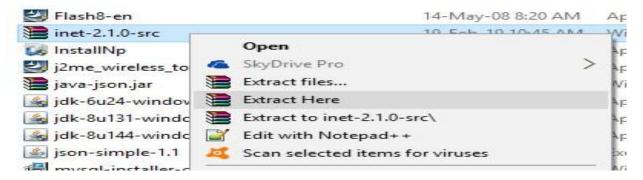

1. Download Omnet++ version 4.2.2 from https://omnetpp.org/omnetpp.

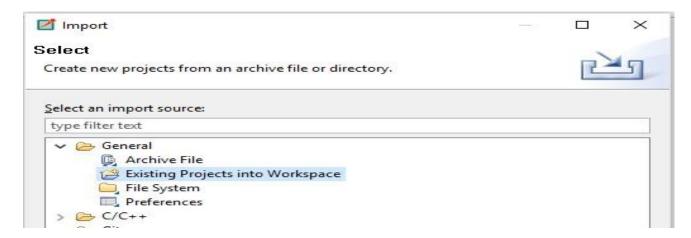

2. After downloading the zip, extract it.

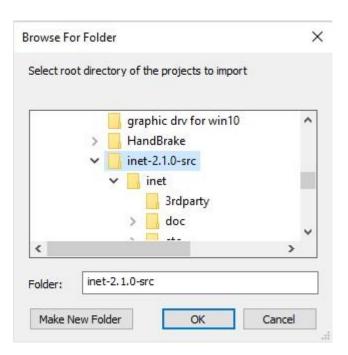

- 3. Now Omnetpp-4.2.2 folder has been created.
- 4. Open the folder and Double click on mingwenv.
- 5. A command prompt will open. Type the command I. ./configure
- II. make
- 6. When both commands get executed then omnet++ is installed in your system.
- 7. To check whether it is installed or not type the command omnetpp in the command prompt and omnetpp will get started. If it does not start then try to reinstall.
- 8. After installing Omnet++, we need to install inet framework version 2.1.0 which is specially designed for wireless simulation. You can download inet framework from below link. https://inet.omnetpp.org/Download.html
 - INET 2.2.0 for OMNeT++ 4.2 (What's New)
 - INET 2.1.0 for OMNeT++ 4.2 (What's New)
 - INET 2.0.0 for OMNeT++ 4.2 (What's New)
 - INET 201111118 for OMNeT++ 4.2
 - INET 20110225 for OMNeT++ 4.1
- 9. After downloading the Inet 2.2.0 unzip the files.

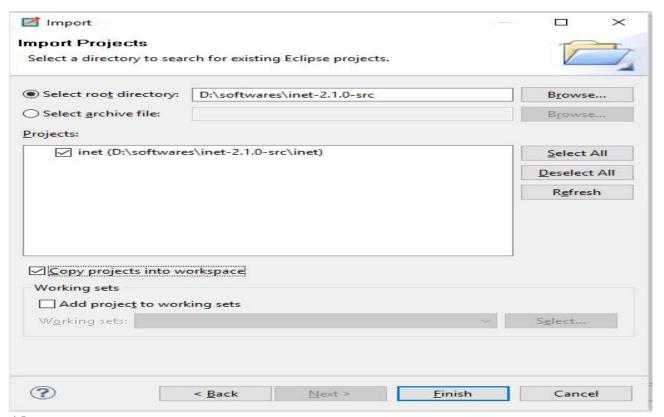

- 10. After extracting inet-2.1.0-src folder will be created.
- 11. Open the Omnet++ idle.
- 12. Click on File > Import. A window will appear in that click on General > Existing Projects in Workspace.

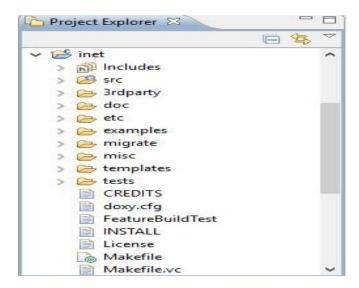

13. Click next and in the root directory browse for the inet-2.1.0-src folder which was created.

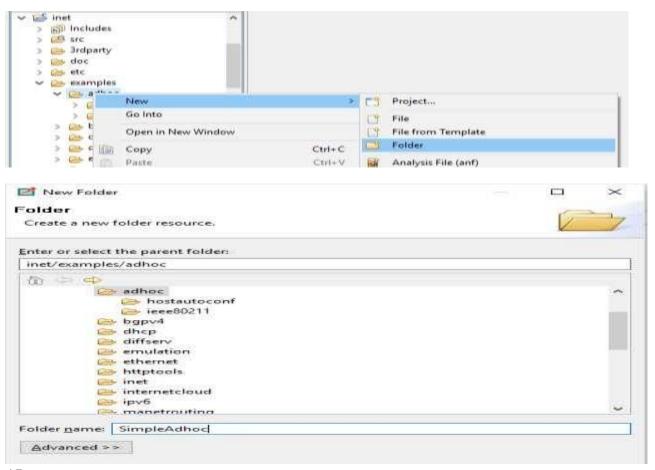

14. Click the checkbox to copy the projects into the workspace and then Finish.

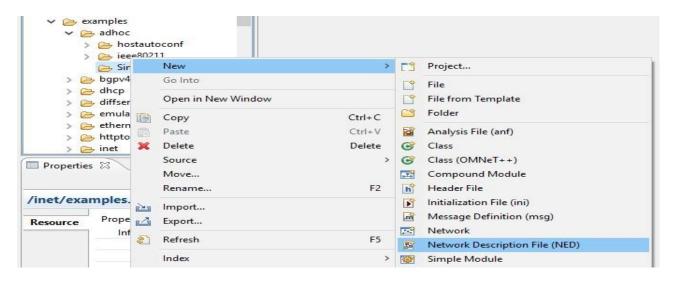

15. An Inet folder will be created in the project explorer.

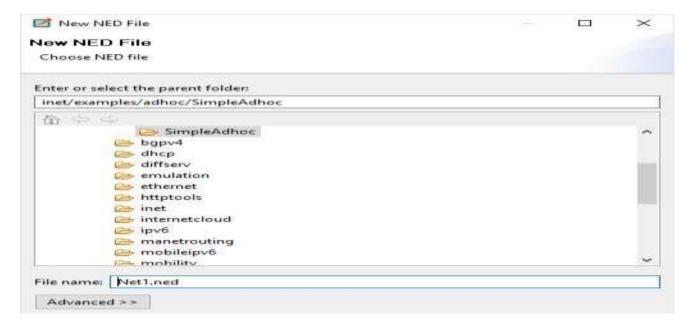

16. Expand the inet folder > examples > adhoc. Right click on adhoc > New > Folder as SimpleAdhoc

17. Right click on SimpleAdhoc > New > Network Description File (NED). Name the file as Net1.

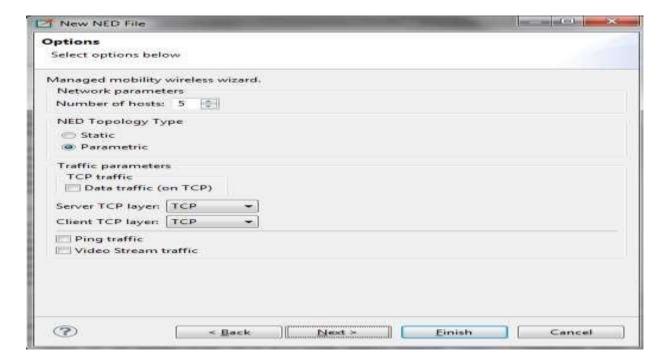

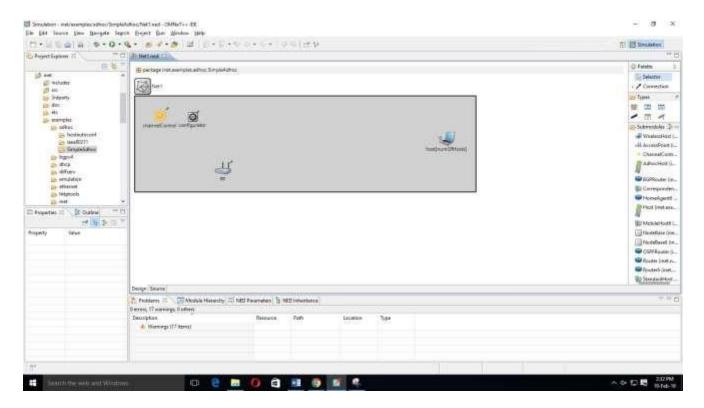

18. Select New Managed Mobility Wireless Network Wizard and Click Next.

19. Configure as follow.

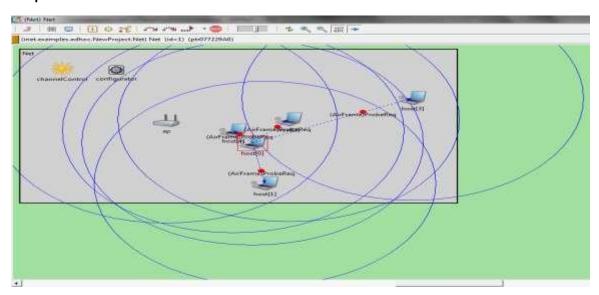

20. Click on Finish.

- 21. To configure, Right click on inet folder > Run as > Run Configurations. Select Net1 > Browse the directory where the project is > Apply > Run.
- 22. Now try to execute by right click on ned file Run as-1-Omnet++ simulation.

Output:

Practical-5

Understanding, Reading and Analyzing Routing Table of a network

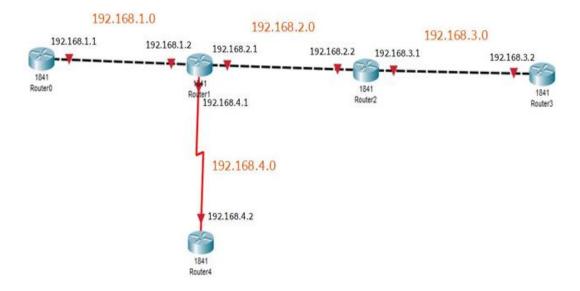

Aim: To create a network and set the routing path, understand and analyze the routing table of the networks

Software Used: Cisco Packet Tracer 7.2.0.026

Theory: A routing table is similar to a distribution map in package delivery. Whenever a node needs to send data to another node on a network, it must first know where to send it. If the node cannot directly connect to the destination node, it has to send it via other nodes along a route to the destination node. Each node needs to keep track of which way to deliver various packages of data, and for this it uses a routing table. A routing table is a database that keeps track of paths, like a map, and uses these to determine which way to forward traffic. A routing table is a data file in RAM that is used to store route information about directly connected and remote networks. Nodes can also share the contents of their routing table with other nodes. The primary function of a router is to forward a packet towards its destination network, which is the destination IP address of the packet. To do this, a router needs to search the routing information stored in its routing table. The routing table contains network/next hop associations. These associations tell a router that a particular destination can be optimally reached by sending the packet to a specific router that represents the next hop on the way to the final destination. The next hop association can also be the outgoing or exit interface to the final destination. An example of Routing Table

Network destination	Netmask	Gateway	Interface	Metric
0.0.0.0	0.0.0.0	192.168.0.1	192.168.0.100	10
127.0.0.0	255.0.0.0	127.0.0.1	127.0.0.1	1
192.168.0.0	255.255.255.0	192.168.0.100	192.168.0.100	10
192.168.0.100	255.255.255.255	127.0.0.1	127.0.0.1	10
192.168.0.1	255.255.255.255	192.168.0.100	192.168.0.100	10

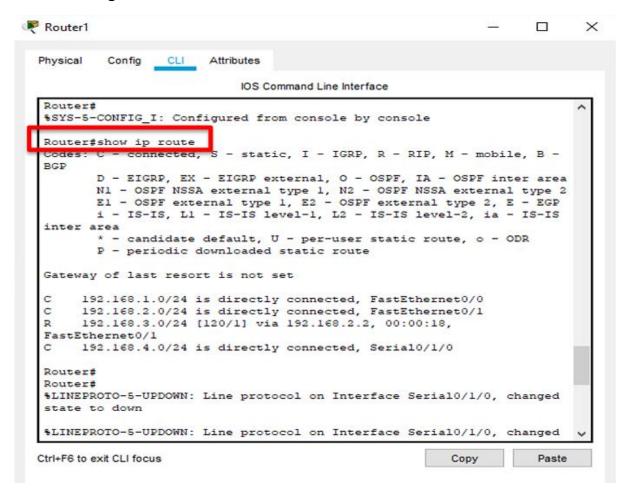

Consider the following topology:

The ip addresses are configured on the given interfaces of the Routers.

The Routing path is also set using RIP.

The following command is executed in the CLI mode of Router1.

We get the following Routing information from Router1

C 192.168.1.0/24 is directly connected, FastEthernet0/0

C 192.168.2.0/24 is directly connected, FastEthernet0/1

R 192.168.3.0/24 [120/1] via 192.168.2.2, 00:00:18, FastEthernet0/1

C 192.168.4.0/24 is directly connected, Serial0/1/0

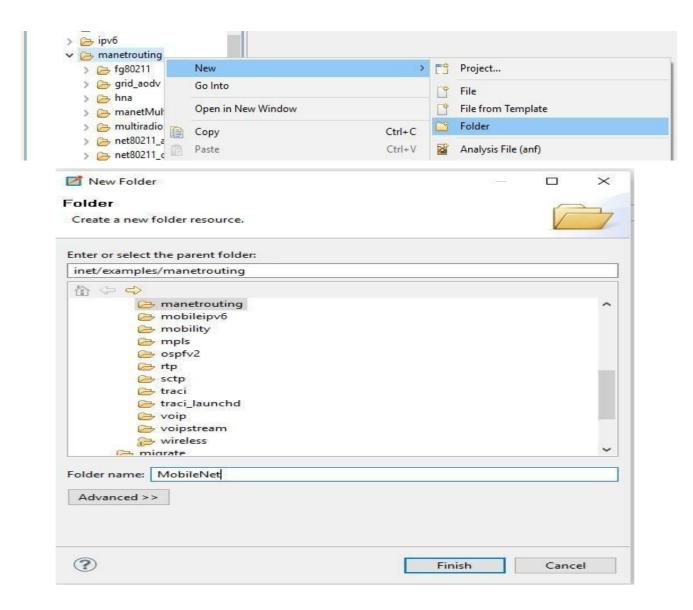

Which is the required output

Practical -6

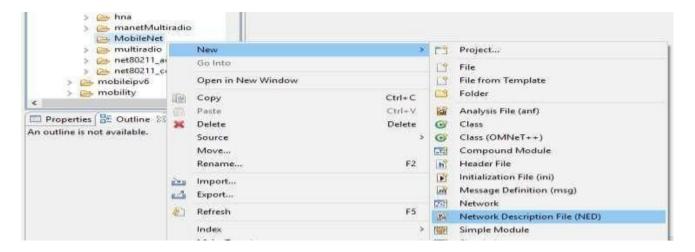

Aim: Create a basic MANET implementation simulation for Packet animation and Packet Trace

Steps:

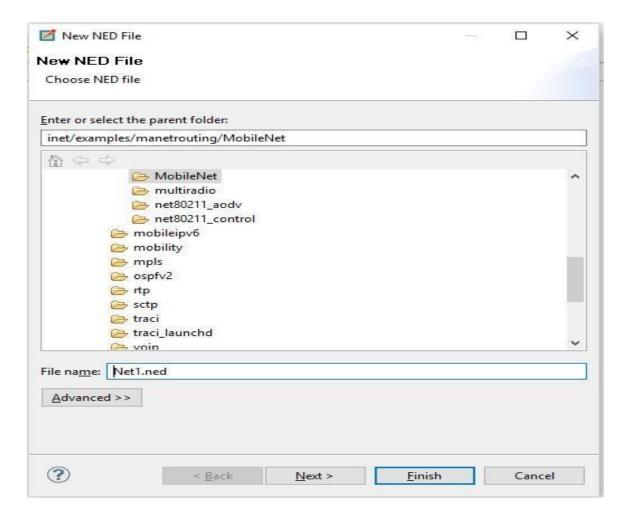

- 1. Open Omnet++ idle.
- 2. Expand the inet folder > examples > manetrouting. Right click on manetrouting > New > Folder as MobileNet.

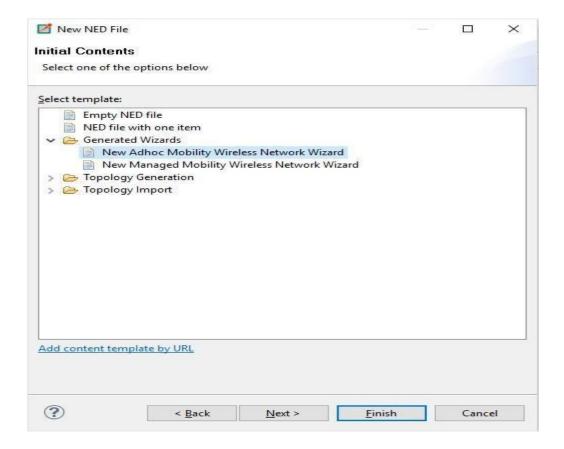

3. Right Click on MobileNet > New > Network Description File (NED).

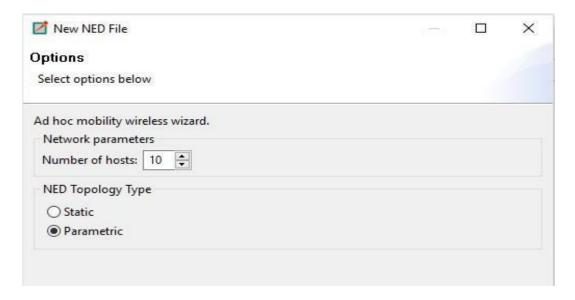

4. Name the file as Net1 and Click Next.

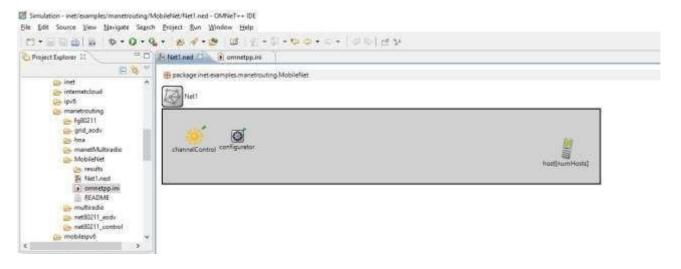

5. Select New Adhoc Mobility Wireless Network Wizard and Click next.

6. Configure as follow.

7. Click on Finish.

- 8. To configure, Right click on inet folder > Run as > Run Configurations. Select Net1 > Browse the directory where the project is > Apply > Run.
- 9. Below is the code that will be available in source part of net1.ned once configured.

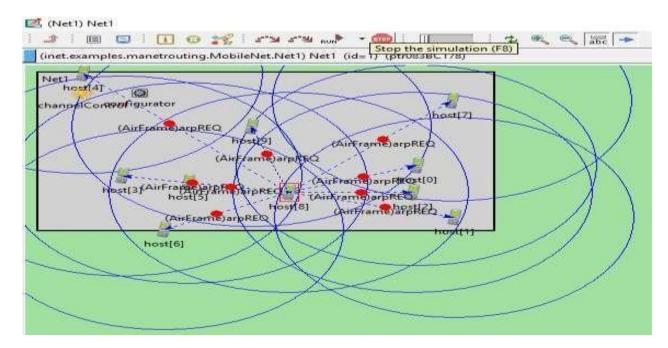

```
package
   inet.examples.manetrouting.MobileNet
   // numOfHosts: 10
   // parametric: true
   // static: false
   import
   in et. network layer. autorouting. ip v4. IP v4 Network Configurator;\\
   import inet.nodes.inet.AdhocHost; import
   inet.world.radio.ChannelControl;
   network Net1
   {
   pa
   ra
   m
   et
   ers
        int numHosts;
   submodules:
        host[numHosts]: AdhocHost
        {
   parame
WSN(Wireless Sensor Network)
```

```
@display("r=,,#707070");
        }
        channelControl: ChannelControl
        {
   parame
   ters:
   @displa
   y("p=60
   ,50");
        }
        configurator: IPv4NetworkConfigurator
        {
          @display("p=140,50");
        }
   }
   10. A file omnetpp.ini will be created with the following source code.
   [General]
   network =
   Net1
   #record-
   eventlog =
   true
   #eventlog-message-detail-pattern = *:(not declaredOn(cMessage) and not

**.wlan[*].mgmt.frameCapacity = 10
**.wlan[*].mac.address = "auto"
**.wlan[*].mac.maxQueueSize = 14
```

WSN(Wireless Sensor Network)

- **.wlan[*].mac.rtsThresholdBytes = 3000B
- **.wlan[*].mac.retryLimit = 7
- **.wlan[*].mac.cwMinData = 7
- **.wlan[*].mac.cwMinMulticast = 31
- **.wlan[*].radio.transmitterPower = 2mW
- **.wlan[*].radio.thermalNoise = -110dBm
- **.wlan[*].radio.sensitivity = -85dBm
- **.wlan[*].radio.pathLossAlpha = 2

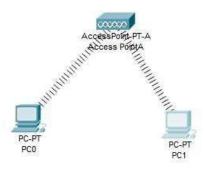

**.wlan[*].radio.snirThreshold = 4dB

Practical -7

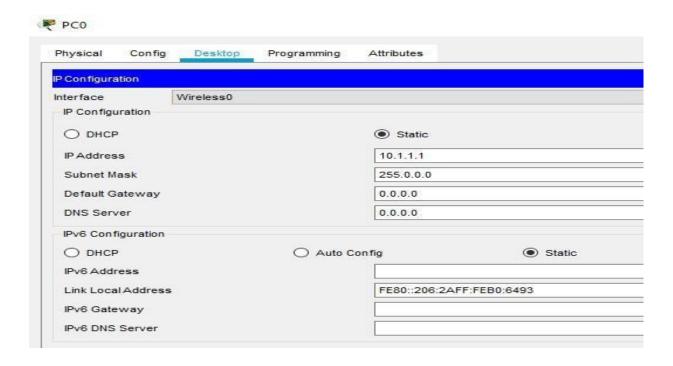

Aim: Implement a Wireless sensor network simulation.

Steps:

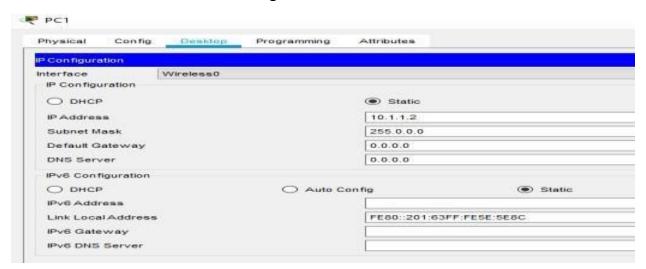

1. Create the following network using AccessPoint-PT-A and PC-PT.

- 2. Click on PCO and click on Physical tab.
- 3. Turn off the CPU and remove the FastEthernet module and install PT-HOST-NM-1W-A and turn On the CPU.
- 4. A connection will be made between Accesspoint and PCO.
- 5. Click on PC1 and click on physical tab.
- 6. Repeat step 3 and see if the connection is done between PC1 and Accesspoint.
- 7. Click on PCO and set the IP config.

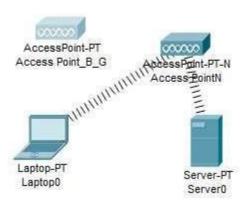

8. Click on PC1 and set the IP config.

9. Test Access PointA

- a. Ping PC1 (10.1.1.2) from PC0. The ping should succeed.
- b. Ping Laptop0(10.1.1.3) and Server0 (10.1.1.4) from PCO. The pings should fail.
- 10. Create the following network using Accesspoint-PT, Accesspoint-PT-N, Laptop and Server.

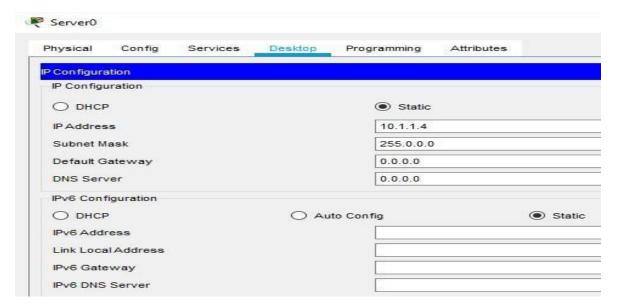

- 11. Click on Laptop and click on Physical tab.
- 12. Turn off the Laptop and remove the PT-LAPTOP-NM-1CFE module and install PT-LAPTOPNM1W and turn On the Laptop.
- 13. A connection will be made between Accesspoint-PT-N and Laptop.
- 14. Click on Laptop and set the IP config.

- 15. Click on Server and click on Physical tab.
- 16. Turn off the Server and remove the PT-HOST-NM-1CFE module and install PT-HOST-NM-1W and turn On the Server.

- 17. A connection will be made between Accesspoint-PT-N and Server.
- 18. Click on Server and set the IP config.

19. Test Access PointN

- a. Ping Server0 (10.1.1.4) from Laptop0. The ping should succeed.
- b. Ping PC0 (10.1.1.1) and PC1 (10.1.1.2) from Laptop0. The pings should fail.
- 20. Now Turn off the port of AccesspointN and Test Access Point_B_G
 - a. Turn on Port1 on Access Point_B_G and turn off Port1 on Access PointN. Laptop0 and Server0 should associate with Access Point B G.
 - b. Ping Server0 (10.1.1.4) from Laptop0. The ping should succeed.

Practical -8

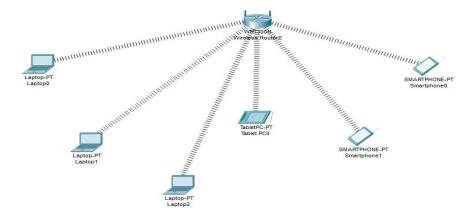

Aim: To create MAC protocol simulation for a Wireless Sensor network

Theory:

Consider the following topology, we use some wireless hosts instead of Wireless sensors. The working in both the cases is same

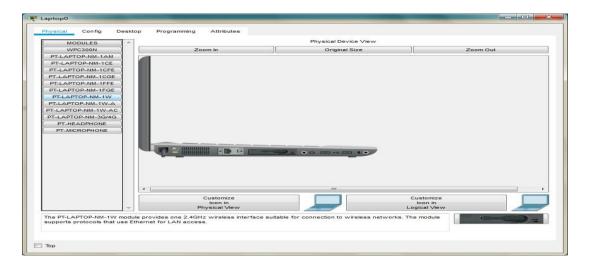

In the given topology we use

- i) Laptops 3
- ii) Smart phone 2
- iii) iii) Tablet 1
- iv) Wireless Router

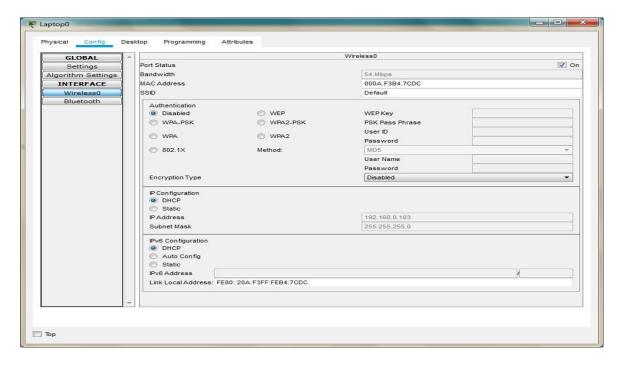

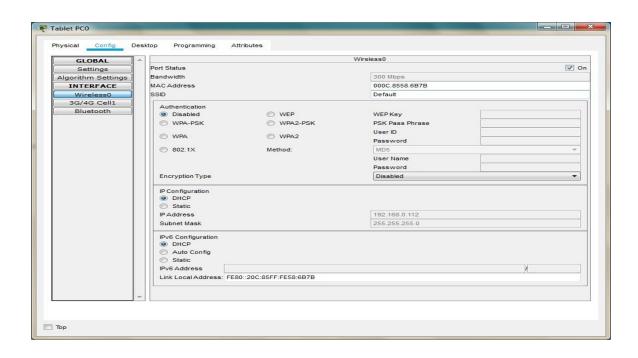

Smart phones and Tablet have a wireless interface by default, while the laptop does not has a wireless interface, we need to add the interface in all the laptops

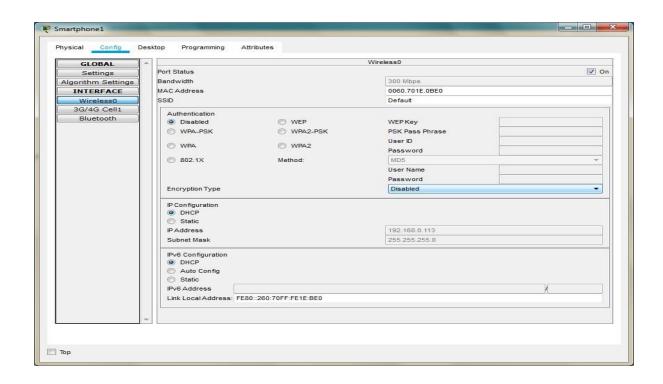

Adding the wireless interface to each Laptops as follows

Copy the MAC address of each component as follows

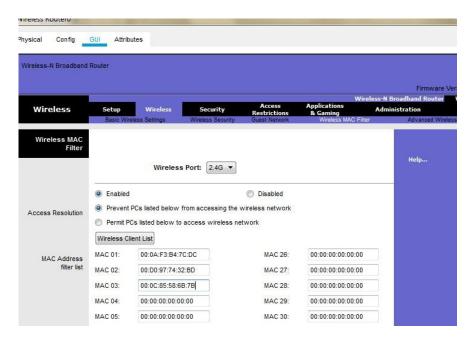

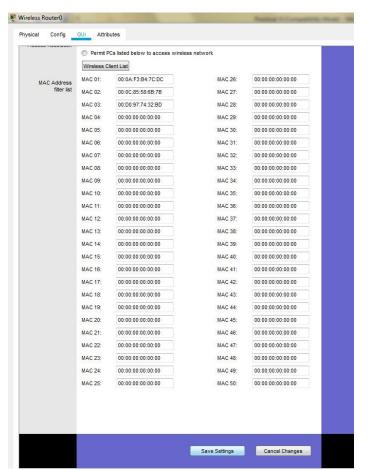

We note the following MAC addresses and convert them to the following form

Component	MAC Address	Converted MAC address
Laptop0	000A.F3B4.7CDC	00:0A:F3:B4:7C:DC
Laptop1	0001.4269.6539	00:01:42:69:65:39
Laptop2	0060.5CB8.B919	00:60:5C:B8:B9:19
TabletPC	000C.8558.6B7B	00:0C:85:58:6B:7B
SmartPhone0	00D0.9774.32BD	00:D0:97:74:32:BD
SmartPhone1	0060.701E.0BE0	00:60:70:1E:0B:E0

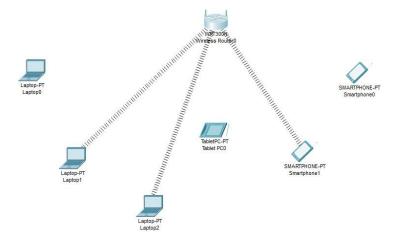

Now we add few addresses in the wireless MAC filter of the Wireless Router and then use the given options for either allow or deny the Wireless access

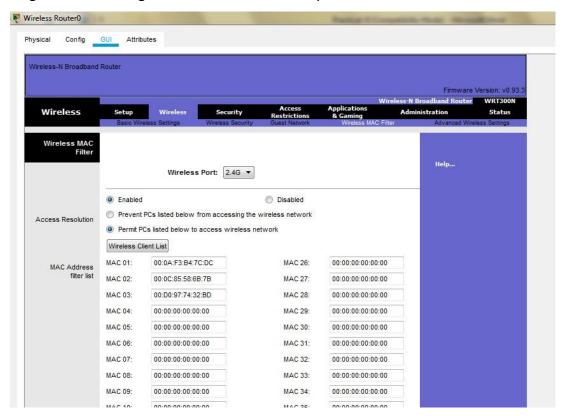

As seen in above screen shot we add the MAC address of Laptop0, TabletPC SmartPhone0 in the list so as to deny them accessing the Wireless network and then save the settings

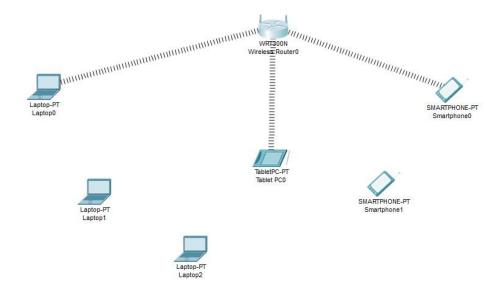

The result so obtained is as shown; the three devices denied any wireless connectivity

Similarly we can change the setting so that the above devices get wireless connectivity and the remaining devices do not get the wireless connectivity

And save the setting and get the following

Practical -9

Aim: Simulate Mobile Adhoc Network with Directional Antenna.

Steps:

Create the following network.

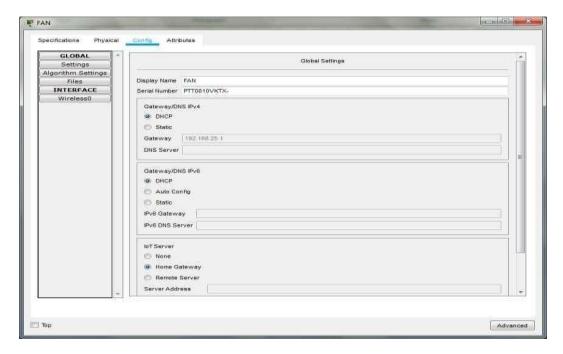

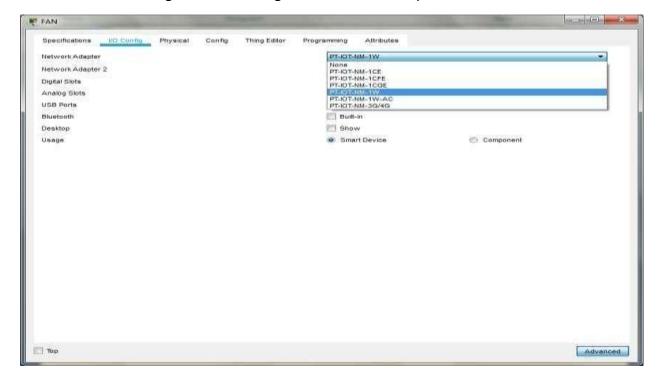

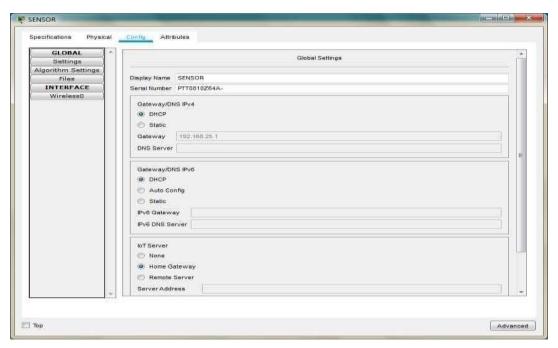

Click on the Fan and do the following

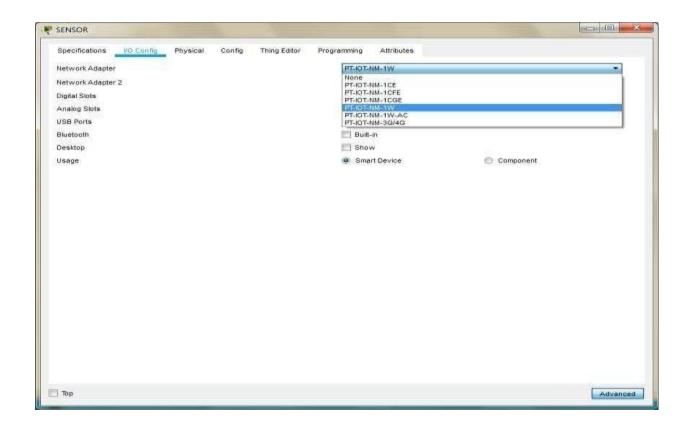

In the Advanced setting do the following for the Network adapter

For the motion Detector sensor do the following

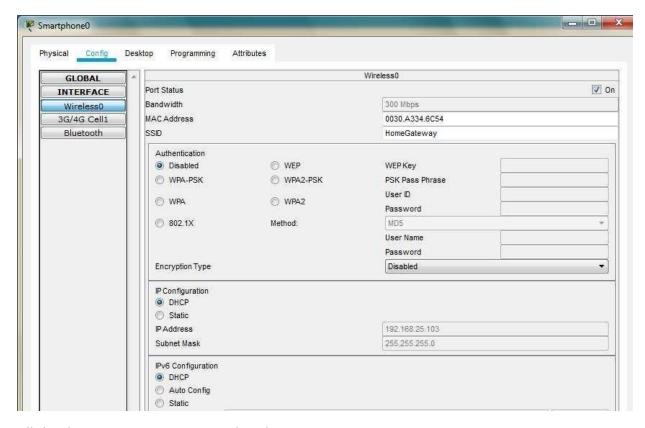

In the Advanced setting do the following for the Network adapter

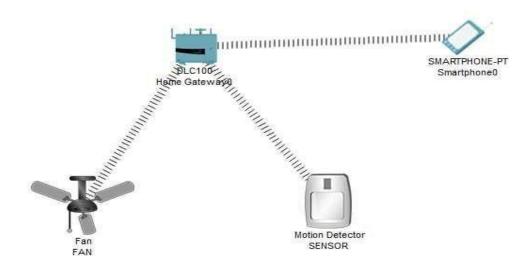

For the smartphone change the SSID to the SSID in the Home Gateway0

As seen above the SSID is HomeGateway, we use the same and set the SSID in the Smartphone

All the devices are now connected to the Home Gateway

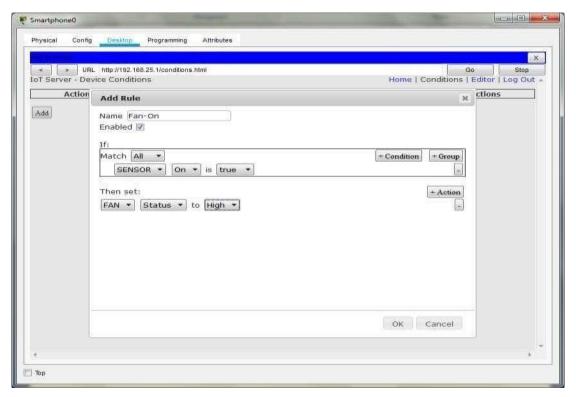

Now open the Web browser of the SmartPhone and type the IP address of the HomeGateway

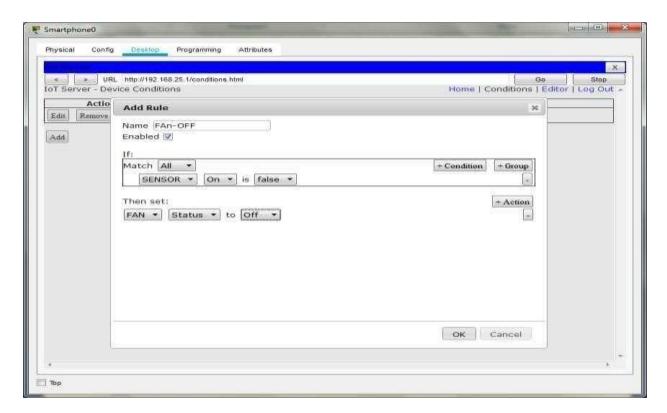

Username: admin

Password: admin

After logging click on conditions and do the following

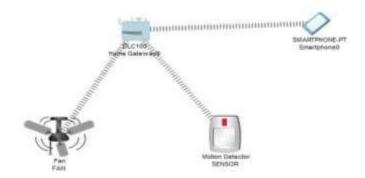

Add another condition as follows

Press the go button after adding the two conditions

In order to turn ON the fan Press the ALT key and left-click the mouse over the Sensor

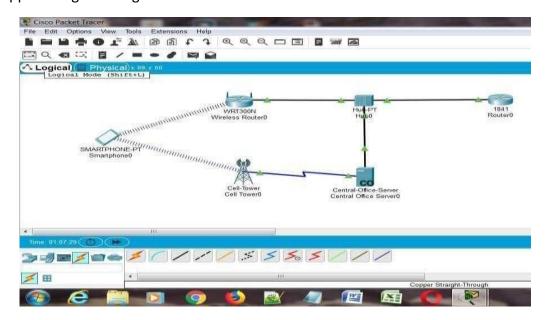

Practical -10

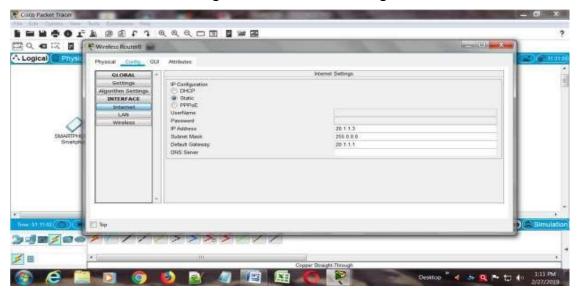

Aim: Create a mobile network using Cell Tower, Central Office Server, Web browser and Web Server. Simulate connection between them.

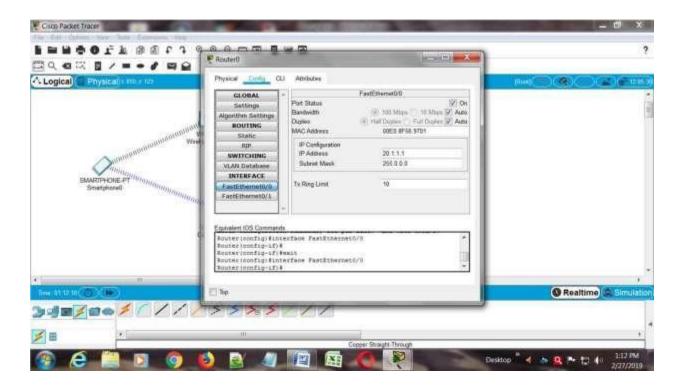

Steps:

- 1. Create a network using smartphone, wireless router WRT300N, Hub-pt, 1841 Router, centralofficeserver, Cell-Tower.
- 2. Connect cell tower and central office server using coaxial cable.
- 3. Connect wireless router WRT300N, Hub-pt, 1841 Router, central-office-server using copper straight through wire.

- 4. Click on wireless router.in config tab select internet.in internet choose ip configuration as static and set IP address and default gateway.
- 5. Click on router 1841. In config tab select interface and give IP address.

6. Click on smartphone and ping router1841

```
Physical Config Desktop Programming Attributes

Command Prompt

Pinging 20.1.1.1 with 32 bytes of data:

Request timed out.

Reply from 20.1.1.1: bytes=32 time=24ms TTL=254
Reply from 20.1.1.1: bytes=32 time=18ms TTL=254
Reply from 20.1.1.1: bytes=32 time=21ms TTL=254

Ping statistics for 20.1.1.1:

Packets: Sent = 4, Received = 3, Lost = 1 (25% loss),
Approximate round trip times in milli-seconds:

Minimum = 18ms, Maximum = 24ms, Average = 21ms

C:\>ping 20.1.1.1

Pinging 20.1.1.1 with 32 bytes of data:

Reply from 20.1.1.1: bytes=32 time=18ms TTL=254
Reply from 20.1.1.1: bytes=32 time=19ms TTL=254
Reply from 20.1.1.1: bytes=32 time=23ms TTL=254
Reply from 20.1.1.1: bytes=32 time=17ms TTL=254

Ping statistics for 20.1.1.1:

Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:

Minimum = 17ms, Maximum = 23ms, Average = 19ms
